Scenario:
A retail company is migrating its e-commerce platform to a containerized microservices architecture. The platform has two key microservices:

- **Product Service** – manages product catalog details.
- **Order Service** – handles customer orders and depends on the Product Service to validate product availability.

As a DevOps engineer, you have been assigned to **dockerize, and test** these services.

After that, include one more new service named **Payment Service** – calculates the total bill as per the items included in the Order Service
